

Gastrinoma

Gastrinoma is a tumor with increased gastrin production, most often located in the pancreas. It is based on the G-cells of the pancreatic islets of Langerhans. Gastrinoma grows slowly but may be locally invasive; but more often it metastasizes. Due to increased gastrin production, high secretion of gastric juice with a high content of HCl and proteinases occurs, which leads to the repeated formation of peptic ulcers, especially in the duodenum, but they can also occur in the stomach, esophagus or jejunum. In 50% of cases, the patient develops diarrhea. The disease caused by excess of gastrin is called **Zollinger-Ellison syndrome**.
