

Phospholipids

This article has been translated from WikiSkripta; ready for the **editor's review**.

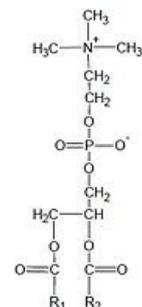

Phospholipids, or glycerol phospholipids, are derivatives of phosphatidic acid (glycerol-3-phosphoric acid). According to the type of substituent attached to phosphatidic acid, phospholipids are further divided into:

1. Phosphatidylcholines (lecithins)
2. Phosphatidylethanolamines (kephalins)
3. Phosphatidylserines
4. Plazmalogens
5. Phosphatidylinositols

Phosphatidylcholines (lecithins)

- They contain choline, a quaternary nitrogen base
- They are a part of the cell membrane
- A large part of the body's supply of choline (important for the transmission of nerve impulses)
- Waxy, colorless compounds with hydrophilic and hygroscopic features
- They form colloid solutions in the water, create internal salts, reduce surface tension, good emulsifying agents
- Easily hydrolyzed in the body due to the action of phospholipases
- Dipalmitoyllecithin - surfactant

 For more information see *Phosphatidylcholine*.

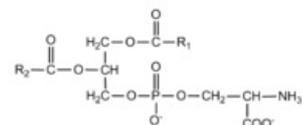

Phosphatidylch

Phosphatidylethanolamines (kephalins)

- They contain ethanolamine bound by an ester bond to the second acid group of phosphoric acid
- Similar character as phosphatidylcholines

Phosphatidylserine

- It contains serine amino acid
- It is found in most tissues

Phosphatidylserine

Plazmalogens

- The fatty acid is replaced at position 1 by an ether-linked higher unsaturated alcohol
- Similar to lecithins and kephalins
- Synthesized on peroxisomes by desaturation of 3-phosphoethanolamine derivatives (requires molecular oxygen, cytochrome b5, NADPH+ + H+ for the synthesis)
- There are 3 types of plasmalogens: choline, ethanolamine, serine
- Most of the phospholipids in mitochondria are plasmalogens
- Choline plasmalogen, the so-called platelet-activating factor (PAF), is a mediator of hypersensitivity, acute inflammatory reaction and anaphylactic shock. The IgE antigen stimulates its production. When PAF is released, platelet aggregation and serotonin secretion occur

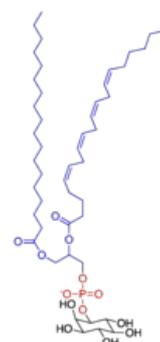

Phosphatidylinositol

- They contain inositol, a sugar alcohol
- Part of cell membranes, where they significantly influence its permeability
- A source of arachidonic acid, which is the starting material for the formation of eicosanoids
- Important for the transport of fats by blood and lymph
- After stimulation by a certain hormone, phosphatidylinositol-4,5-bisphosphate is split into diacylglycerol and inositol triphosphate - these substances act as an internal signal or second messenger
