

# Pseudomonas

Template:Infobox - bakterie

The genus **Pseudomonas** belongs to the so-called gram-negative non-fermenting bacteria. The groups **Stenotrophomonas** and **Burkholderia** also belong to this group. Due to their common characteristics and traits, these genera can be put into context, in the medical sense, these genera are important mainly in terms of nosocomial infections.

Pseudomonas aeruginosa is characterized by its green-blue pigment

## Taxonomy

The taxonomy of the genus *Pseudomonas* is constantly renewed, the current classification is as follows:

- class **Gammaproteobacteria**
- order **Pseudomonadales**
- family **Pseudomonadaceae**
- genus **Pseudomonas**
- this genus includes many species of bacteria, the most important of which include:
  - *P. aeruginosa*
  - *P. alcaligenes*
  - *P. fluorescens*
  - *P. mendocina*
  - *P. putida*
  - *P. stutzeri*

## Occurrence

They are especially common in **humid environments**. So they inhabit **soil, surface water, plants**, but mainly medically important – **hospital equipment**. In pathogenesis, the products of these bacteria and the structure of their cell wall, specifically its outer parts formed by lipopolysaccharides, play a role. It is the construction of this membrane that is responsible for the resistance of bacteria to antibiotics. **Multi-resistance** to antibiotics is a major therapeutic problem. However, today it is undergoing a renaissance of colistin in parenteral form, which is often the last "in vitro" effective drug.<sup>[1]</sup>

## Significant Representatives

The most important member of the genus *Pseudomonas* is the bacterium ***Pseudomonas aeruginosa***.

 For more information see *Pseudomonas aeruginosa*.
