

Sertoli cells

Sertoli cells are **pyramid-shaped cells** with an elongated to triangular nucleus with a low volume of heterochromatin and a prominent nucleolus.

They arise from the surface epithelium of the gonads. It is located in the **testicles**, more precisely in the **germinal epithelium** of the **seminiferous tubules**. They attach to the basal membrane and their **protrusions** extend between the individual developmental stages of the sperm, often protruding into the lumen of the seminiferous tubule. They are **connected to each other** by tight junctions and nexus. **Their main functions** are nutrition and protection of spermatogenic elements (they are the only ones in contact with blood - the **hematotesticular barrier**), the ability of phagocytosis, the production of testicular fluid and anti-müllerian hormone.

Scheme of spermiogenesis in the testis. 1-basal lamina, 2-spermatogonia, 3-spermatocytes of the 1st order, 4-spermatocytes of the 2nd order, 5-spermatid, 6-mature spermatid, 7-Sertoli cell', 8-zonula occludens
