

# Shigellosis

**Shigellosis or bacillary dysentery** (bacterial dysentery) is an acute, highly infectious diarrheal disease with a typical mucus and blood in the stool, often accompanied by fever and abdominal cramps.

<b>Originator</b>	<i>Shigella</i> spp.
<b>Transmission</b>	direct contact, contaminated water and food
<b>Incubation time</b>	1-4 days [1]
<b>Clinical picture</b>	diarrhea with blood and mucus, fever, chills, chills
<b>Infectiousness</b>	highly infectious
<b>Therapy</b>	rehydration, ATB: co-trimoxazole, fluoroquinolones, rifaximin

## Etiology and pathogenesis

*Shigellas* are gram-negative stationary sticks. The genus *Shigella* is divided into:

- *Shigella dysenteriae* – group A shigellosis (*Shiga-Kruse dysentery*),
- *Shigella flexneri* – group B shigellosis,
- *Shigella boydii* – group C shigellosis,
- *Shigella sonnei* – group D shigellosis.

They are sensitive to disinfectants but survive in acidic environments for several hours. Bacteria multiply rapidly in the **small intestine**, but only in the large intestine is the **intestinal epithelium damaged**, into which shigellas penetrate and multiply in them. Subsequently, they also attack neighboring enterocytes, which then die of necrosis. Macroscopically, we see an **inflammatory to necrotically altered mucosa**, especially the **distal sections of the colon**. *Shigella* is characterized by the production of toxins, which make it easier to get intracellularly and induce apoptosis. In addition, *Shigella dysenteriae* serotype I produces **shiga toxin** with the properties of cytotoxin, neurotoxin, and enterotoxin and cause more severe diseases. Shiga toxin is very similar to verotoxin of enterohemorrhagic *E. coli*.

## Epidemiology

The source of infection is **contaminated food, sick or convalescent person**. It is an exclusively human disease, it is a typical disease of "dirty hands", occurring epidemically in **groups where it is difficult to maintain hygiene** (children's camps, social institutions, psychiatric hospitals, etc.). The alimentary transmission occurs through infected food, especially milk and water. The **infectious dose** is only 10-100 bacteria.<sup>[1]</sup> Shigellosis is the most infectious bacterial intestinal infection. The global incidence is estimated at **200 million cases** per year.<sup>[2]</sup> Due to hygienic measures, the disease is uncommon in the Czech Republic – about 400 cases per year, of which 20% of diseases are imported. Children are most often affected during the summer months.

## Clinical symptoms

- Sudden fever (febrile convulsions and symptoms of meningeal irritation in children), chills,
- cramping abdominal pain, located more to the left,
- diarrhea – first large watery stools, with a decrease in temperature it turns into numerous small stools with blood and mucus,
- painful tenesmus,
- vomiting rarely.

The course depends on the age, nutrition of the patient and his general condition. A complication may be hemolytic uremic syndrome in strains producing shiga toxin or intestinal abscess.

## Diagnosis

We use stool culture to confirm the diagnosis. In case of ambiguity, we realize a serotyping.

## Therapy

- rehydration,
- antibiotics – therapeutic and epidemiological effect,
  - co-trimoxazole,
  - fluoroquinolones,
  - rifaximin,
  - azithromycin,
- probiotics,
- drugs decreasing the frequency of diarrhea are not suitable (risk of toxic megacolon).

## Differential diagnosis

We also consider differential diagnosis of EIEC, EHEC, amoebiasis, campylobacter infection, yersiniosis, and non-typhoid salmonellosis.
