

Spirochetes

Spirochetes are a phylum of fine, spirally wound bacteria . They usually reach a size of 5-250 µm (sometimes up to 500 µm). It does not stain very well with conventional bacteriological techniques.

distinguish the following genera of spirochetes:

- ▪ *Borrelia* ;
- *Leptospira* ;
- *Treponema* .

Genus Borrelia

Representatives of the genus *Borellia* are spiral, motile bacteria that are difficult to cultivate on artificial culture media . It dyes well with aniline dyes. They parasitize on humans and animals and their intermediate hosts are arthropods.

Borrelia hermsii

Borrelia hermsii is the cause of recurrent fever , which is mediated by ticks or lice.

Borrelia burgdorferi

Borrelia burgdorferi

More detailed information can be found on the *Borrelia burgdorferi* website .

Borrelia burgdorferi is a long, spirally coiled bacterium of 4-30 µm . It causes multiorgan involvement - Lyme disease . Its vectors are infected ticks. Because it is microaerophilic, it requires a complex culture medium (N-acetylglucosamines, amino acids, vitamins, nucleotides). Its generation time is relatively long, namely 12 hours .

Borrelia recurrentis

Borrelia recurrentis is up to 30 µm long, the bacterium is coiled up to 5-10 irregular threads It is the cause of recurrent fever as well as *Borrelia hermsii*. The carrier is infected with lice. The moment it multiplies in the host, a fever develops. The fever subsides after a few days. After about 3-10 days , recurrence occurs (hence its name). A suitable antibiotic is tetracycline .

Genus Leptospira

The genus *Leptospira* includes spiral, motile bacteria that feed saprophytically or parasitically. They parasitize mainly on animals, they infect humans exceptionally. If an infection occurs, then it mainly affects people working with animals (anthroponosis).

Leptospira interrogans

Leptospira biflexa

Leptospira biflexa are saprophytic bacteria living in moist soil.

Leptospira interrogans

Leptospira interrogans is a type of bacteria that spreads to all tissues, damages the endothelium , causing hemorrhage and jaundice . It is obligatorily aerobic. Bacteriologists are considering dividing it into 7 species , which would be related to clinical units. Pathogenicity factors probably include bacterial toxins , cytotoxic factors such as phospholipases, etc. *Leptospira icterohaemorrhagiae* is the cause of Weil's disease. It grows well in cultures with bovine albumin . Generation time is long. It lasts approximately 7 to 16 hours .

Affected skin by tropical frambezia

Genus Treponema

The genus *Treponema* includes spiral motile bacteria, which measure 5-20 µm and have regular threads . It includes both pathogenic and non-pathogenic species (anaerobic species). Non-pathogenic species occur, for example, in the oral cavity and can trigger a "false alarm" precisely because of their antigenic relationship to pathogens. It has a very long cultivation time in the range of 10 to 30 hours (the longest of the spirochet strain) .

Treponema pertenue

Treponema pertenue is the causative agent of tropical frambezia. It is characterized by difficult differentiation from *Treponema pallidum* and sensitivity to penicillin treatment .

Treponema carateum

Treponema pallidum

Treponema carateum occurs predominantly in America and causes a chronic skin condition called pint. The disease is treated with penicillin .

Treponema pallidum

See the *Treponema pallidum* page for more information .

Treponema pallidum is indistinguishable in shape and size from other species. It causes a disease called syphilis . It does not grow in culture media or chicken embryos, so intratesticular inoculation (rabbit testes) is used for cultivation. It is very sensitive to external influences.
