

# Bowel malrotation and volvulus

'Malrotation means disorder of rotation of the intestine or failure of its attachment to the back wall of the abdomen. A normal intestine rotates counterclockwise. A. mesenterica sup acts as the axis of rotation. An unfixed intestine predisposes to *volvulus* (knotting of the intestinal hinge) and to obstruction. It is sometimes associated with asplenia or congenital heart defects.

Volvulus of the small intestine.

## Clinical picture

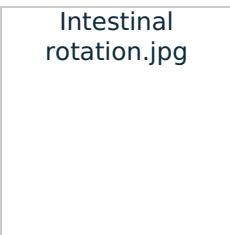

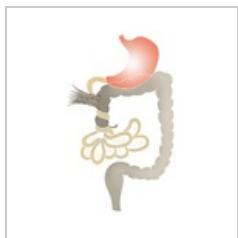

- Symptoms of acute or recurrent NPB,
- symptoms appear shortly after birth or at any time during the first year of life.

## Diagnosis

- On the X-ray, we can see the distribution of air - there are no bubbles in the area of the cecum,
- rotation failure will be confirmed by irrigography.

## Therapy

- Surgical.

Volvulus of the small intestine.

Ladd's syndrome - unrotated cecum and duodenal compression by peritoneal bands.

Intestinal rotation during embryonic development. The black line represents the entrance to the umbilical cord.
