

Hemicrania continua

Hemicrania continua is a primary headache that is **more common in women**, lasts **at least 3 months** without relief, is **unilateral** with a variable course of **moderate to severe intensity** with **at least one of the following symptoms**:

- conjunctival injection, lacrimation, or both;
- nasal congestion, rhinorrhea, or both;
- ptosis , miosis or both;[1]

and **relief with Indomethacin treatment** [2]

PET can show changes in the mesencephalus , which distinguishes hemicrania from migraine and cluster headache . **Indomethacin** is used in therapy at a dose of 75-150 mg / day and is also used to prevent new episodes. Indomethacin treatment can be lifelong, although the dose may be reduced over time.[1]
