

# Location of efflorescences

The so-called **predilection localizations** are places typical for a certain disease, they are caused by both external and external influences. For example , *scabies* on delicate skin, etc.

## Most common localizations

- **intertiginous localization** - places of wet inflammation and skin duplication; intertrigo , yeast and fungal diseases
- **organ localization** - disease of certain skin organs
- **seborrheic localization** - in places with a higher representation of sebaceous glands (pales, face, above the sternum, between the shoulder blades and the genital area)
- **solar localization** - parts of the body most often exposed to the sun (face, neck, hands...)
- **embolization localization** - caused by hematogenous spread, mainly in drug and infectious exanthemas (chest, hips, abdomen, flexor surfaces of the hand, inner surfaces of the thighs)
