

Low-molecular-weight heparins

Low-molecular-weight or **fractionated heparin** (*LMWH*) acts in the early phase of blood coagulation mainly by *binding to factor Xa with antithrombin*, unlike high-molecular heparin, which also irreversibly blocks thrombin activity.

The main representatives include:

1. Nadroparin (Fraxiparine);
2. Enoxaparin (Clexane);
3. Dalteparin (Fragmin);
4. Parnaparin;
5. Sulodexide.

- **Administration** subcutaneously, most often in the abdomen, but it is also possible to administer intravenously in exceptional cases, such as in patients on hemodialysis or with unstable angina pectoris.^[1]

▪ **Indications:**

1. **Treatment** and **prophylaxis** of acute deep vein thrombosis and pulmonary embolism (VTE).
2. **Bridging** - bridging the necessary warfarin withdrawal before a planned surgery.^[2]

▪ **Comparison to high-molecular-weight heparins:**

Compared to high-molecular-weight heparins, they are **safer**, have a **longer-lasting effect** and show significantly **fewer adverse effects** (heparin-induced thrombocytopenia, bleeding).

Antikoagancia - Nepřímé inhibitory trombinu / faktoru Xa
