

Myxedema Coma

Myxedema coma is the escalation of the symptoms of hypothyroidism into a life-threatening condition.

Etiology

Untreated or poorly treated hypothyroidism + provocative moment (stress, cold, infection, injury, surgery, medication, alcohol).

Klinical picture

- Decrease in body temperature (up to 30 °C),
- hypoventilation + increased retention CO₂,
- extreme drowsiness; gradually progresses to coma,
- bradycardia,
- hyponatremia + hypercapnia → arrhythmia → heart failure + cardiac arrest.

Diagnostics

- In peripheral etiology significantly ↑ TSH + ↓ fT4, hypercapnia, ↓ Na⁺ + Cl⁻, ↑ CK, liver function tests, LDH,
- assessment cortisol + ACTH.

Therapy

- Glucocorticoids (e.g. hydrocortisone 100 mg i.v./d – current renal insufficiency cannot be excluded in most patients),
- adjustment of water + electrolyte balance,
- levothyroxine (200-500 µg/d gastric tube),
- preventively antibiotics, heart failure therapy, gradual warming,
- ALV (in respiratory insufficiency), pacing (in severe bradycardia).
