

Relative risk

Relative risk is an indicator describing the **relationship between exposure to risk factor and health consequences**. Determines the degree of association detected:

- RR = 1 means that the given factor has no influence on the development of the disease,
- RR > 1 means the exposure is a **risk** factor,
- RR < 1 means that the exposure is a **protective** factor.

Relative risk is expressed as a ratio of incidence of disease in the exposed and non-exposed group. It should be distinguished from odds ratio and absolute risk.

$$RR = \frac{p_{\text{expo}}}{p_{\text{neexpo}}}$$
