

Short series of biochemical tests

We identify intestinal bacteria (within the **Enterobacteriaceae** family) on the basis of the biochemical properties of individual genera. We use a short series of biochemical reactions for this. It is a series of test tubes in which various biochemical tests are performed. The summary of results is always characteristic of a certain genus. Tests include: fermentation of glucose, H₂S formation, urease formation, Simmons citrate, and indole formation.

Glucose fermentation + gas formation

- Glucose solution with bromothymol blue + gas
- **Principle:** the reaction uses pH changes during fermentation of sugars + the gas is in the test tube upside down, if the bacteria produce gas, they accumulate in it and form a bubble.
- **Result:**
 - *Positive with bubble* - yellow (glucose fermentation) + bubble
 - *positive without bubble* - yellow (glucose fermentation)
 - *negative* - green-blue (no fermentation).

H₂S formation

- Hajny medium (ferric ammonium citrate indicator)
- **Principle:** lead sulfide elimination causes medium blackening.
- **Result:**
 - *positive* - blackening
 - *negative* - red, yellow

Urease formation

- Medium with urea
- **Principle:** urease produced by bacteria breaks down urea in the medium, which leads to an increase in pH and the medium turns pink.
- **Result:**
 - *positive*: medium color change
 - *negative*: green, yellow

Simmons citrate

- medium with sodium citrate and bromothymol blue as an indicator
- **Principle:** bacteria use sodium citrate as a carbon source, ammonia is released, this leads to the increase in the pH of the environment and bluing of the medium
- **Result:**
 - *positive*: medium bluing
 - *negative*: green, yellow

Indole formation

- Hottinger broth (contains tryptophan) + Ehrlich (paradimethylaminobenzaldehyde) or Kovács reagent
- **Principle:** tryptophan is degraded by some bacteria, producing indole (indole-positive bacteria), the presence of which can be demonstrated by the addition of an agent.
- **Result:**
 - *positive*: red ring on the surface
 - *negative*: yellow ring

Resolution of the most important bacteria [1]

	Distinguishing the most important bacteria						
	glucose	lactose	sucrose	mannitol	urea	hydrogen sulfide	indole
Escherichia Coli	+g	+	+-	+	-	-	+
Citrobacter freundii	+g	+-	-,+	+	-	+	-
Klebsiella pneumoniae	+g	+	+	+	+	-	-
Enterobacter aerogenes	+g	+	+	+	-	-	-
Proteus mirabilis	+g	-	r	-	+	+	-
Proteus vulgaris	+g	-	+	-	+	+	+
Morganella morganii	+g,+	-	-	-	+	-	+
Providentia rettregi	+g,+	-	r	+-	+	-	+
Salmonella typhi	+	-	-	+	-	+	-
other salmonellas	+g	-	-	+	-	+	-
Shigella	+	-	-	+-	-	-	+-
Serratia	+g	-	+	+	r	-	-
Yersinia enterocolica	+	-	+	+	+	-	-

- fermentation with gas formation: +g
- fermentation without gas formation: +
- negative reactions: -
- differing results: r
